These working papers are preliminary research documents published by the IUJ research institute. To facilitate prompt distribution, they have not been formally reviewed and edited. They are circulated in order to stimulate discussion and critical comment and may be revised. The views and interpretations expressed in these papers are those of the author(s). It is expected that the working papers will be published in some other form.

# Perceptions to climatic changes and cooperative attitudes toward flood protection in Bangladesh

Moinul Islam\*    Koji Kotani†

June 30, 2014

## Abstract

Bangladesh is vulnerable to climatic changes, and there has been a serious debate about the occurrence and the relationship with the frequency of flooding. For example, in Dhaka, further flood controls are claimed to be necessary due to a change of climatic patterns and more frequent flood events. Despite the importance of this topic, it has received little research attention. Thus, we examine (i) whether a temporal change in climate variables is occurring, (ii) local people's perceptions to climate and (iii) cooperative attitudes toward flood controls. We conducted face-to-face surveys with 1,011 respondents of different social and demographic strata and seven experts in Bangladesh. Using these data, we first derive a temporal trend of climate variables and analyze how closely people's perceptions align with the climate data. Second, we examine the willingness to pay for flood controls as a proxy of cooperative attitudes, and characterize the determinants in relation to perceptions to climate as well as socio-economic characteristics. We obtain the following principal results. First, some climate variables are identified to exhibit clear upward or downward trends, but most people correctly perceive such temporal changes. More specifically, people's perceptions and our statistical analysis are identical in the qualitative changes of climate. Second, people who correctly perceive climatic changes tend to express a higher WTP than those who do not. Overall, these findings suggest that accurate climate perceptions are keys to increasing cooperation into managing climate change and related disasters.

**Key Words:** Climate change, perception, willingness to pay, flood

## Nomenclature

MSL Mean sea level

WTP Willingness to pay

# 1 Introduction

Bangladesh is one of the most disaster-prone countries in the world because of its geographical setting (Brouwer et al., 2007). Bangladesh is part of the Bengal Basin, one of the largest geosynclinal countries in the world. It lies in the northeastern part of South Asia, between latitudes  $20^{\circ} 34'N$  and  $26^{\circ} 38'N$  and longitudes  $88^{\circ} 01'E$  and  $92^{\circ} 41'E$  and has a gross area of approximately  $147,570 \text{ km}^2$ . Approximately 80% of the country's land is the floodplains of three large rivers, the Ganges, the Brahmaputra and the Meghna. Only 10% of Bangladesh is  $1m$  above the mean sea level (MSL) and one-third is under tidal influence.

Bangladesh is likely to be affected by more intense and frequent flood events in the foreseeable future due to potential climate changes and the associated MSL rise (Schiermeier, 2011a,b). This is an issue of great concern, because the location and geography of Bangladesh make it both particularly susceptible to the effects of climate change, and extremely difficult to protect. Despite the importance of this issue, few studies have examined people's perceptions and behavior with regard to climate and flood controls in relation to historical climate data. Thus, this paper seeks to address these issues.

There is a rich body of literature on climate change and its potential impact on society. Some research claims that humans are a main cause of altered climatic patterns (Stern, 2006, Cline, 2007, Schiermeier, 2011b). For instance, Rockstrom et al. (2009) suggest that we have already exceeded the planet's "safe operating space" in the climate system, and a warmer world has more extreme rainfall occurrences. This is because the amount of water vapor that the atmosphere holds increases rapidly with temperature. Rainfall data also reveal significant increases of heavy precipitation over much of northern hemisphere land and the tropics. Overall, these tendency of climate are reported to increase the frequency of floods (Parry et al., 2007, Pall et al., 2011, Min et al., 2011).

Although scientific evidence confirms occurrences of climatic change, people's knowledge, perceptions to climate, and the relationship of these factors with attitudes are equally important. This is because these issues are directly linked to the formulation of policies for climate change (Tobler et al., 2012b,a). Several works demonstrate that abstract explanations of climate change

28 without actual experiences of these “changes” are ineffective to convey what is actually occurring  
29 and to affect people’s mindsets and behavior (see, e.g., Spence et al., 2011). The greatest barrier  
30 to public perceptions of climate change is the difficulty of cultivating correct perceptions of tem-  
31 poral trends and the natural variability of climate, especially among people whose daily life is not  
32 dependent upon weather or climate (Hansen et al., 1998, Balling Jr. and Cerveny, 2003, Hansen  
33 et al., 2012). In this situation, critical questions arise “How well does or can an individual detect  
34 climate change, given the stochastic nature of local weather and climate from day to day and year  
35 to year?” and “How do correct perceptions of climate relate to attitude and actions?”

36 In developed countries, numerous studies have examined the above questions. Previous re-  
37 search claims that highly educated people understand climate, and express their knowledge in  
38 surveys (Viscusi and Zeckhauser, 2006). Moreover, people who are more confident about the issue  
39 tend to be more cooperative, expressing a higher WTP for actions to prevent adverse effects of  
40 climatic change (Semenza et al., 2008, Akter and Bennett, 2011, Akter et al., 2012, Spence et al.,  
41 2011). In contrast, other studies show that some socio-cultural and psychological factors impede  
42 preventive actions for climate change, even when people are knowledgeable about or confident  
43 about the issue (Henderson-Sellers, 1990, O’Connor et al., 1999, Leiserowitz, 2006, Dessai and  
44 Sims, 2010, Osbahr et al., 2011). Therefore, the relationship between knowledge (or understand-  
45 ing) and attitude toward climate change remains unsolved.

46 In developing countries, there have been relatively few studies on this subject. For instance,  
47 several works have used surveys to examine local people’s understanding of climate change (Ved-  
48 wan and Rhoades, 2001, Adelekan, 2005, Vedwan, 2006, Mertz et al., 2009). These studies  
49 have found that people in developing countries often demonstrate less understanding of climate  
50 change compared to people in developed countries and that they tend to qualitatively misunder-  
51 stand the changes of key climate variables. Furthermore, few previous works have examined the  
52 link between local people’s understanding and their cooperative attitudes or actions toward climatic  
53 change.

54 Given this gap in the literature, we study the perceptions of local people to climate change

55 in Dhaka, Bangladesh as a representative case in a developing country. We then analyze the re-  
56 lationship between the perceptions of people and cooperative attitudes to flood controls (climate  
57 change-related disasters). More specifically, we address the extent to which people in Bangladesh  
58 correctly perceive climate change by considering both climate data taken from weather stations  
59 and perceptions elicited in surveys. Furthermore, we examine whether or not people who correctly  
60 perceive climate change are more cooperative toward flood controls. In this analysis, we use a  
61 “willingness to pay” (WTP) measurement for flood controls as a good proxy of cooperative atti-  
62 tudes because the occurrence of climate change in Bangladesh is known to increase the frequency  
63 of flooding (Schiermeier, 2011b).<sup>1</sup>

64 For the aforementioned purposes, we conducted a questionnaire survey of 1,011 respondents  
65 and seven experts to elicit their perceptions on key climate variables as well as their WTPs for flood  
66 controls. Additionally, we obtained corresponding climate data from three meteorological stations  
67 located in the same area. Using these two data sets, we first derive a temporal trend of climate  
68 variables, examine people’s perceptions and compare them with actual climate data. Given these  
69 results, we derive a binary variable that takes the value of 1 when a respondent possesses correct  
70 perceptions of a climate event or variable, at least in a qualitative manner, and otherwise takes  
71 the value of 0. Using the binary variable of climate perceptions and other factors as independent  
72 variables, we run a Tobit regression of WTP for flood controls to characterize people’s cooperative  
73 attitudes in relation to their perceptions of climate.

74 Based on this approach, our research addresses the following questions:

- 75 1. How close are people’s perceptions of climate change to the climate data obtained from  
76 weather stations?
- 77 2. What factors affect WTP for flood damage protection, and do correct perceptions of climate  
78 change lead to higher WTP?

79 None of the above questions have been explicitly addressed in the literature. Our analysis yields

---

<sup>1</sup>It is likely that most Bangladeshi people have difficulty reaching a common understanding of the terminology for climate change, so we avoid using this terminology to assess cooperative attitudes.

80 the following main results. First, some key climate variables show clear upward or downward  
81 time trends, but most people correctly perceive the temporal trends of the climate variables at least  
82 in a qualitative manner. More specifically, both people's perceptions and our statistical analysis  
83 are identical in the qualitative changes of climate variables. Second, those who correctly perceive  
84 climatic changes tend to express a higher WTP than those who do not, implying that the WTP is  
85 positively affected by correct perceptions of climate. Overall, these findings suggest that informa-  
86 tion provision and correct perceptions of climate are keys to improving cooperation in addressing  
87 climate change and possible related disasters.

## 88 **2 Study area and data collection**

### 89 **2.1 Study area**

90 The Meghna Basin area of Bangladesh was selected as a study area because it is vulnerable  
91 to climatic changes and frequent flooding. Within the Meghna Basin area in central Bangladesh,  
92 the administrative Upazilas—Narsingdi Sadar and Raipura were chosen. The two Upazilas are  
93 characterized by different production potentials. Figure 1 is a map of the research area. Raipura  
94 has relatively higher agricultural potential, whereas Narsingdi Sadar has lower agricultural but  
95 higher industrial potential. The household is a unit of analysis, because it is the decision-making  
96 unit in livelihood processes, with the senior and earning male person household member as the  
97 decision maker. The survey was conducted in 2011 and 2012.

98 [Figure 1 about here.]

99 The climatic conditions in Raipura and Narsingdi Sadar have relatively uniform temperatures,  
100 high humidity, and heavy rainfall. Heavy rain usually occurs from June to September. The average  
101 annual temperature ranges from 13°C to 35°C. The rivers in the Upazilas are Meghna (the most  
102 important), Old Brahmaputra, Arial Khan and Kakan. Because Raipura Upazila and Narsingdi  
103 Sadar Upazila are plain lands, the Meghna floods, especially in the rainy seasons.

## 2.2 Questionnaire and field survey

The structured questionnaire is employed to collect the data on household socio-economic characteristics, such as socio-demographic status, information sources at the household level, approximate losses in four major floods (in 1988, 1998, 2004, and 2007 in Bangladesh), WTP for flood protection, and perceptions of weather or climate changes. Regarding the elicitation of WTP, we use an open-ended question format, following Markantonis et al. (2013) and Ghanbarpour et al. (2014) that also elicited WTP for flood controls. To be more specific about the flood event, we asked respondents their WTPs toward preventive measures and controls when the flood event of the same scale with each of major flood events that occurred in 1988, 1998, 2004 and 2007 is assumed to occur in the future. For example, we asked respondents their WTP under the scenario that the flood like the one that occurred in 1988 is assumed to occur in the future. We elicited WTP under each scenario for the flood events in 1998, 2004 and 2007, respectively. We chose this way, because setting a specific scenario by mentioning the past flood events give respondents a relatively uniform understanding for flooding in our pilot survey.

The participants were local people from various backgrounds including farmers, businessmen, teachers, public officials and others. The heads of the households usually answered the survey questions. Our survey also included seven well-reputed experts in Bangladesh specializing in meteorology and flood controls, who also answered questions related to weather or climate changes, perceptions of climate risks, and whether six seasons are becoming four seasons in study areas. The questionnaire was developed interactively. Theoretical findings and primary field surveys were used to design a first draft of the questionnaire. Then, the questions were carefully modified to ensure that understanding and answering these questions would not require an academic background or expert knowledge.<sup>2</sup> Another questionnaire was designed to elicit expert opinions on the various issues of climate and flooding, which was used only for the experts' interviews. The results of experts' interviews are not used in the statistical analysis that follows, however, these results were referenced when necessary for qualitative judgments in the analysis. Fifteen villages

---

<sup>2</sup>The original questionnaire is in Bengali. The translated version is available upon request.

130 in Narsingdi Sadar Upazila were selected; one was excluded because of poor accessibility. Of 14  
131 selected villages in Raipura, all were successfully surveyed. In each village, households were cho-  
132 sen by random sampling. The interviews were conducted by 16 field research assistants during the  
133 period from December 24, 2011 to January 14, 2012. The survey involved 1,011 residents from 14  
134 villages, including low-, medium- and high-density population areas.

## 135 **2.3 Meteorological data**

136 Daily weather data were collected from the Bangladesh Meteorological Department. The data  
137 includes daily rainfall, daily average temperature, daily maximum temperature and daily minimum  
138 temperature. First, to capture local climatic changes in the last 25 years, we examined data from  
139 three nearby weather stations from 1985 to 2010 to ensure the robustness of our qualitative re-  
140 sults. An average value for the climate data taken from the three stations was used as a benchmark  
141 throughout this analysis. The average distances of the stations from our survey areas are as follows:  
142 Dhaka, 38.4 *km*, Comilla, 71.44 *km* and Chandpur, 77.64 *km*. We found no significant qualita-  
143 tive difference among these three stations with respect to the data quality and the corresponding  
144 climatic pattern, and the data are of good quality with few missing observations. Therefore, we  
145 present the analysis using the data from the three stations. Finally, figure 2 summarizes the data  
146 collection procedure consisting of a primary field survey, a household survey, an expert interview  
147 and the collection of meteorological data.

148 [Figure 2 about here.]

## 149 **3 Methodology and data analysis**

### 150 **3.1 Climatic and weather change**

151 Rainfall and temperature are the most significant climate variables affecting human activities.  
152 Therefore, we focus on climate variables related to rainfall and temperature for our analysis. For

153 farmers, the distribution and periodicity of rain events and temperature variation within a growing  
154 season or a single year and the effectiveness of the rains in each precipitation event may affect  
155 farming practices. For other land users, these rainfall and temperature events may have some  
156 importance for everyday life.

157 We selected eight important climate variables that affect the daily life of local people. Table 1  
158 shows the variables chosen to identify a change in climatic pattern and the corresponding reasons  
159 for their selection. We analyze these climate variables over the years 1985 to 2010 and derive a  
160 temporal trend in climate variables. We plot historical observations of climate variables for each  
161 month or each season. Finally, to determine the overall trend in climate variables, we estimate a  
162 coefficient of the time trend by running regression analysis. The estimated regression is drawn on  
163 the time series plot of climate variables.

164 [Table 1 about here.]

165 Respondents were asked what the weather and climate were like 25 years ago to access their  
166 perceptions of normal climate patterns. We then asked what the weather and climate are like today  
167 and posed some further questions related to changes in climate variables over time. Each respon-  
168 dent was asked to give at least a qualitative answer of “increasing,” “no change,” or “decreasing”  
169 for these questions. Their perceptions of the changes in climate variables over time were com-  
170 pared to the meteorological records collected from three nearby stations where this field work took  
171 place.<sup>3</sup>

172 To judge whether a respondent’s perception is qualitatively consistent with the time series  
173 climate data or not, we employ the following procedure. First, we draw the time series plot of  
174 the climate variable of our interest, say, average summer temperature, from 1985 to 2010. Second,  
175 we run the simple regression by taking a time trending variable as an independent variable, yielding

---

<sup>3</sup>We initially attempted to incorporate questions related to the perceptions of the risk or standard deviations of climate variables in a survey. However, our pilot survey revealed that it is difficult to create a uniform understanding of this issue among Bangladeshi people partly due to the difference in educational background compared to developed countries. Therefore, we avoided directly asking questions related to the risk of climate change. Instead, we attempted to translate this risk-related question into frameworks that could be easily understood (e.g., an increase in frequency of extreme rainfall).

176 an estimated coefficient of time trending. If the estimated coefficient is more than 1%, we consider  
177 it as “increasing.” If it is less than  $-1\%$ , it is “decreasing.” Otherwise, no change. Our survey  
178 also elicits each respondent’s perception to each climate variable; increasing, decreasing and no  
179 change. If the respondent’s perception is the same as the qualitative change concluded from a time  
180 trending regression, we consider the perception to be correct or consistent with time series climate  
181 data. Note that we use the 1% criteria to judge whether a certain climate variable is increasing,  
182 decreasing or no change based on our experts’ survey. The experts say that an annual or monthly  
183 1% increase (decrease) as a time trend becomes more than 10% increase (decrease) in 10 years  
184 later. It is considered significant enough to say an increase or decrease in the context of Bangladesh  
185 climate.

### 186 **3.2 WTP for flood controls**

187 To identify the determinants of people’s cooperative attitudes toward flood damage protection, a  
188 Tobit regression is applied, because our samples for WTPs include approximation 150 observations  
189 of zero. In our survey, respondents indicated their WTP for flood protection by considering the  
190 four major floods that occurred in the last 25 years in Bangladesh. The basic assumption is that  
191 WTP may be a good proxy for people’s cooperative attitudes and may depend on their socio-  
192 economic household characteristics, climate stimuli, correctness of perceptions and experiences.  
193 More formally, the underlying regression is formulated as follows:

$$194 \quad \text{WTP} = f(\text{socioeconomic characteristics, experiences and correctness of perceptions}) + \epsilon,$$

195 where

- 196 • WTP represents the willingness to pay for flood protection. In our sample, WTP 1988, WTP  
197 1998, WTP 2004 and WTP 2007 correspond to the respondents’ WTP to collectively control  
198 the damage under the scenario that a flood event like the one that occurred in 1988, 1998,  
199 2004 and 2007 is assumed to occur in the future.

- 200 • Socio-economic characteristics correspond to the variables of education, income, conditions,  
201 family structures, residential time, some knowledge about climate change, and advance ac-  
202 cess to flood information.
- 203 • Experience represents whether respondents have suffered from floods in the 1988 and 1998.  
204 When they reported to have suffered, this variable indicates the corresponding economic loss  
205 in each flood event.
- 206 • Perception represents whether respondents correctly perceive seasonal and climate changes.  
207 For this, we only choose climate variables and the corresponding perceptions that are directly  
208 relevant to the occurrence of flooding. More specifically, all climate variable related to  
209 rainfall and precipitation are included in the regression. This perception variable is binary  
210 taking the value of 1 when respondents correctly perceive the time trend of a climate variable  
211 in a qualitative manner. Otherwise, it takes 0.<sup>4</sup>
- 212 •  $\epsilon$  is an error term.

213 Tables 2 and 3 provide the definition of explanatory variables and the summary statistics of all the  
214 variables included in the Tobit regressions, respectively.

215 [Table 2 about here.]

216 [Table 3 about here.]

---

<sup>4</sup>In this judgment of whether the dummy variable of correct perception is set to 1, we use the coefficient of the temporal trend for a climate variable estimated from the time series climate data in the previous section. For instance, the coefficient is positive with more than 1% (or negative with less than -1%); we consider it “increasing” (or “decreasing”), and those who answered “increasing” (or “decreasing”) in the survey are considered to have correct perceptions. In some cases, we also obtain the coefficient of a temporal trend that is positive or negative, but very close to zero with the absolute magnitude of less than 1% (e.g., an estimated coefficient of 0.0025 is considered to be no change, since it is less than 1% in absolute value). In such a case, we consider it as no change and the answer “no change” from the respondents is correct. We determine to use this 1% criteria based on our experts’ survey as mentioned earlier.

## 217 **4 Results and discussion**

### 218 **4.1 Climatic change**

#### 219 **4.1.1 Change in rainfall**

220 Figure 3 (in five subfigures) plots the average rainfall on rainy days for each monsoon season.  
221 All four monsoon months in subfigures 3(a), 3(b), 3(c) and 3(d) show that the average monthly  
222 rainfall over each month increased from 1985 to 2010. Pooling the monthly plot from June to  
223 September, subfigure 3(e) also shows the increasing trend over time. The slope of the linear trend  
224 derived from the plot in subfigure 3(e) implies that average rainfall on rainy days increased by  
225 2.28 *mm* within 25 years. Our survey results suggest that people’s perceptions are consistent with  
226 the change in this climate variable. Of 1,011 individuals, 744 respondents, approximately 72.6%  
227 of the sample population, answered “increasing” in the survey and correctly perceived the change  
228 in monsoon rainfall (figure 4, column 1), but 27.4% of the sample population underestimated the  
229 change (figure 4, column 1).

230 [Figure 3 about here.]

231 [Figure 4 about here.]

232 We now aim to identify a consistent trend in the rainfall extremes in monsoon months from  
233 the data analysis. Figure 5 shows that the time trends in monsoon extreme rainfall were generally  
234 positive over the years of our analysis, although a negative trend was found in October. The  
235 overall trend in the data pooled from each month shows an increasing temporal trend from 1985  
236 to 2010 (Subfigure 5(e)). A high percentage of participants (849/1,011, 84%) correctly perceived  
237 the “increasing” trend in the extreme rainy days, but 16% underestimated the change (figure 4,  
238 column 2). Perceptions of extreme rainfall are important for understanding and predicting floods in  
239 monsoon seasons, and our findings of a change in extreme rainy days suggest that the Bangladeshi  
240 people recognize the flooding risk.

241

[Figure 5 about here.]

242

243

244

245

246

247

248

Next, we consider average rainfall for eight months of each year as non-monsoon months, six of them show a downward trend of the rainfall from 1985 to 2010 (figure 6). Although two months show a minor increase, one of them is the month just after the monsoon seasons. We examine the overall trend in this climate variable by pooling the data from all non-monsoon months. Figure 7 shows a 2% decrease in rainfall from 1985 to 2010. People's perceptions of the change agree with the time series plots in figures 6 and 7. Surprisingly, 954 of 1,011 respondents (94.36%) correctly answered "decreasing"; only 5.64% of people overestimated the change (figure 4, column 3).

249

[Figure 6 about here.]

250

[Figure 7 about here.]

251

252

253

254

255

256

257

258

259

260

We now examine the dry spell for individual non-monsoon months and for an overall non-monsoon season. Figure 8 shows that most of non-monsoon months demonstrate an increasing trend or no temporal trend of the longest dry spell. An overall trend derived from pooling the data of all the non-monsoon months also shows a similar outcome, slightly increasing or close to zero (figure 9). We judge that the magnitude of the temporal trend is approximately "no change" where the value of overall temporal trend in the longest dry spell is 0.0042 ( $< 0.01$ ). The exceptions are May and October. This may be because these months are immediately before and after the monsoon months, respectively. A majority of respondents (854/1,011, 84.47%) correctly perceived "no change" in the longest dry spell in non-monsoon months (figure 4, column 4), whereas 15.53% of people underestimated the change.<sup>5</sup>

261

[Figure 8 about here.]

262

[Figure 9 about here.]

---

<sup>5</sup>As mentioned earlier, if the absolute value of the temporal trend is less than 0.01, we consider it to represent "no change."

### 263 4.1.2 Change in temperature

264 Figure 10 shows an increasing trend in the frequency of extremely hot days in summer months  
265 from 1985 to 2010, although the first month of summer shows a decreasing trend due to the ef-  
266 fect of the preceding cold months. The other two months show a stronger effect in this regard,  
267 and the number of extremely hot days in April and May increased by approximately 13% and  
268 38%, respectively, from 1985 to 2010. The number of extremely hot summer days increased by  
269 5% (Subfigure 10(d)). Surprisingly, the surveyed population consistently (886/1,011, 87.64%) an-  
270 swered correctly that the number of extremely hot summer days has increased; only 12.36% of  
271 people underestimated the trend (figure 4, column 5).

272 [Figure 10 about here.]

273 Another strong indicator of climate change in Bangladesh is the change in temperatures. The  
274 three measures of temperature are average daily maximum, minimum and mean, calculated to elu-  
275 cidate the overall trend in summer months. Figure 11 shows a slightly rising trend for March,  
276 April and May (Subfigures 11(a), 11(c) and 11(e)). Aggregating the data from the three months  
277 does not change this trend, irrespective of the minimum, maximum and mean temperatures (Sub-  
278 figures 11(b), 11(d) and 11(f)). The average mean temperature increased by 1.2%, and the average  
279 minimum and maximum temperatures increased by 1.3% and 1%, respectively (temporal trend  
280 lines, subfigures 11(b), 11(d) and 11(f)). The respondents' answers are consistent with this me-  
281 teorological data analysis. 830 respondents (830/1,011, 82.1%) identified an increasing trend in  
282 summer temperatures (figure 4, column 6). However, 17.9% of the respondents underestimated  
283 this change.

284 [Figure 11 about here.]

285 We now investigate the temporal trend of extremely cold days in winter seasons. Figure 12  
286 shows that the number of the extremely winter cold days is decreasing over time ( $-6.6\%$  in aggre-  
287 gated observations from January to December; temporal trend line, subfigure 12(c)). Accordingly,

288 798 respondents (798/1,011, 79%) correctly perceived this trend, and only 21% of the respondents  
289 overestimated the change (figure 4, column 7).

290 Finally, we plot the average daily mean, maximum and minimum winter temperatures, which  
291 have remained relatively constant (figure 13). As expected, 904 respondents (904/1,011, 89.4% in  
292 column 8 of figure 4) correctly perceived “no change”; only 10.6% of the respondents overesti-  
293 mated the change. From the above analysis and from the graphical representation in figure 4, we  
294 conclude that Bangladeshi people correctly perceive the change in climatic patterns over time, at  
295 least from a qualitative perspective. Based on our survey, approximately more than 80% of the  
296 respondents correctly perceived the temporal trends of eight climate variables that are important in  
297 Bangladesh.

298 [Figure 12 about here.]

299 [Figure 13 about here.]

## 300 **4.2 People’s cooperative attitudes and WTP regression**

301 Table 4 represents the regression results for WTP corresponding to floods in 1988, 1998, 2004  
302 and 2007, respectively.<sup>6</sup> The table also contains the marginal effect representing the change in  
303 WTP when an independent variable increases by one unit. The results show that the education of  
304 the head of household is statistically significant and increases WTP for flood damage protection for  
305 all regressions of the floods in 1988, 1998, 2004 and 2007. The magnitudes of the marginal effects  
306 of education on WTP in other regressions are similar, indicating the strong positive relationship  
307 between education and WTP for flood protection.

308 [Table 4 about here.]

309 Household income, house condition, family structure and residential time have the same qual-  
310 itative results on WTP for all of the regressions. These independent variables are statistically

---

<sup>6</sup>Initially age, farmer, type of job, amount of cultivable land and cattle ownership were added to the model. However, they were dropped, because they were not significant in any case of WTP and have no impacts on other independent variables included in the analysis. In other words, we confirmed a robustness of our result.

311 significant and increases WTP for flood protection; the corresponding marginal effects are not  
312 economically negligible. However, household members and household distance from the river  
313 negatively affect the WTP, although not always with statistical significance. This result implies  
314 that WTP declines as the number of household members and the distance from the river increase,  
315 consistent with intuition.

316 Next, we examine the independent variables of Loss 1988 and Loss 1998. As mentioned,  
317 these two variables indicate whether the respondent experienced a large, well-known flood that  
318 occurred in Bangladesh and the corresponding economic damage. Contrary to our hypothesis, the  
319 variables are not economically significant implying that the marginal effect is not large enough to  
320 be economically meaningful. Although some of the regressions show statistical significance, the  
321 experience of these floods does not affect WTP in a practically meaningful way.

322 We turn our attention to the variables of knowledge, information and perceptions related to  
323 flooding and climate change. “Knowledge of climate change” and “advance access to flood infor-  
324 mation” correspond to these key independent variables. In general, table 4 shows strong positive  
325 effects of these variables on WTP for all regressions. This result suggests that people who have  
326 knowledge related to climate change as well as access to information on flooding prior to the event  
327 are willing to pay more for control measures. These results are consistent with previous literature.

328 Finally, we review the perception-related independent variables including “a seasonal change  
329 from six to four seasons,” “precipitation in the monsoon season,” “precipitation in the non-monsoon  
330 months,” and “extremely rainy days.” Recall that these are included as perception-related variables  
331 because they are directly related to the risk of flooding in the study region. Table 4 presents that  
332 all of the coefficients on these perception variables are positive and statistically significant. In  
333 addition, the marginal effect on WTP are economically significant. These results imply that peo-  
334 ple who correctly perceive temporal changes in climate variables tend to exhibit higher WTP. To  
335 the best of our knowledge, this is the first study demonstrating that correct perception to climate  
336 leads to higher WTP or more cooperative attitude toward the mitigation of climate-change related  
337 disasters.

338 Overall, the results of our research, especially related to knowledge and perceptions, suggest  
339 some important implications. It is reported that many people, especially in developed countries, are  
340 skeptical about climatic changes, exhibiting non-cooperative attitudes toward mitigation policies  
341 (see, e.g., Cookson, 2009). Sometimes, these non-cooperative behaviors are attributed to uncer-  
342 tainty and ambiguity associated with the occurrence of climate change. However, our results imply  
343 that these attitudes may be changed if they become to possess correct perception, information and  
344 education regarding climatic changes. In other words, people who have knowledge and informa-  
345 tion as well as who correctly perceive the temporal change of climate variables tend to be more  
346 cooperative. Based on these arguments, we suggest that experience, information provision and  
347 education that can reduce ambiguity (or uncertainty) associated with climate and flooding are keys  
348 to improving cooperation in managing climate change and related natural disasters.

## 349 **5 Conclusion**

350 This paper examined climate data, people's perception to climatic changes and attitudes toward  
351 flood controls in Bangladesh. For the data collection, we conducted face-to-face surveys with 1,011  
352 respondents and seven experts from different socio-economic backgrounds in Dhaka and elicited  
353 their perceptions of climate change and WTP for flood controls associated with climate change.  
354 Our results have some important implications. First, key climate variables are identified to exhibit  
355 clear upward or downward trends suggesting some possibility of a change in climate. However,  
356 most Bangladeshi people in our survey correctly perceive the temporal trends of climate variables.  
357 More specifically, people's perceptions and our statistical analysis of climate are consistent with  
358 each other in that they show the qualitatively same direction of temporal changes. Second, people  
359 who correctly perceive climate changes and have knowledge tend to express a higher WTP than  
360 those who do not, implying that WTP is positively correlated with correct perceptions of climate.  
361 Overall, these findings suggest that information provision and education associated with correct  
362 perceptions of climate are keys to improving cooperation in managing climate change and its

363 related disasters.

364 Finally we note some of our study's limitations. For instance, our survey does not cover all  
365 parts of Bangladesh. We focus only on Dhaka because there are three weather stations nearby with  
366 high-quality of daily climate data and few missing observations. The data quality was crucial to  
367 reliable analysis in our study. In the future, if climate data accumulates in other weather stations,  
368 the same type of analysis should be conducted to produce more robust results. Second, we did  
369 not ask any question explicitly related to people's perceptions of "risks" because we had difficulty  
370 explaining the word "risk" in a uniform way that every respondent could understand. It is our  
371 belief that recognition of risk is another important dimension in the climate-change debate when  
372 climate change includes uncertainty and ambiguity.

373 Although there are some limitations and shortcomings in our study, we believe that the results  
374 of this study could be important in untangling the relationship between people's perceptions and  
375 attitudes toward climatic changes and related natural disasters. We are surprised that a majority  
376 of Bangladeshi people correctly perceive the time trend of climate variables and exhibit higher  
377 cooperative attitudes. However, note that this debate still lacks a policy to translate the willingness  
378 to prevent disasters associated with climate changes into collective action yet. We hope that the  
379 results of our research can serve as a reference for decision making of collective climate-change  
380 policies and disaster management in the future.

Table 1: Climate variables in terms of people’s perceptions and the reason for the selection

| <b>Climate variable</b>                           | <b>Definition</b>  | <b>Reason</b>   |
|---|--|---|
| Average rainfall on rainy days in monsoon months* | Daily average rainfall in rainy days in monsoon months where rainy days are days with $\geq 2$ mm of rainfall.         | Represents rainfall                                       |
| Number of extremely rainy days in monsoon season  | Extreme rainy days in monsoon season where $\geq 100$ mm of rainfall is observed in a single day                       | Indicator of excessive rainfall and flood                 |
| Precipitation in non-monsoon months**             | The average rainfall on rainy days in non-monsoon months where rainy days indicate a day with $\geq 2$ mm of rainfall. | Represents rainfall                                       |
| Longest dry spell in non-monsoon months           | Number of maximum consecutive rainless days in non-monsoon months  | Represents drought and its impact on domestic agriculture |
| Extremely hot days in summer months***            | Number of days in which the daily maximum temperature $\geq 35$ °C   | Responsible for disease outbreaks and natural disasters   |
| Temperatures in summer months                     | Maximum, minimum and mean temperatures in summer months  | Real importance for everyday life and summer agriculture  |
| Extremely cold days in winter months†             | Number of days where the daily minimum temperature is $\leq 13$ °C   | Responsible for damage to agriculture and diseases        |
| Temperature in winter months                      | Maximum, minimum and mean temperatures in winter months  | Real importance for daily life and winter agriculture.    |

\*“Monsoon months” are June, July, August and September.

\*\*“Non-monsoon months” are January, February, March, April, May, October, November and December.

\*\*\*“Summer months” are March, April and May.

†“Winter months” are December and January.

Table 2: Description of explanatory variables used in WTP Tobit regressions

| <b>Explanatory variable</b>                   | <b>Description</b>   |
|---|--|
| Education                                     | Education level of the household head  |
| Household income                              | Monthly income of the household  |
| Household condition                           | Materials of which the house made  |
| Family structure                              | Single family or joint family  |
| Residential time                              | How many years the household has been living in this place                                       |
| Household members                             | Number of household members  |
| Household distance from river                 | Distance of the household from the nearest river   |
| Loss 1988                                     | Total amount of loss from 1988 flood   |
| Loss 1998                                     | Total amount of loss from 1998 flood   |
| Flood preparedness                            | Preparation (to some extent) for flooding  |
| Knowledge of climate change                   | Whether a respondent has some knowledge of climate change  |
| Access to flood information                   | Whether a respondent had access to information on flooding in advance of the event               |
| Perception of change from six to four seasons | Whether a respondent think that there is a seasonal <sup>1</sup> change from six to four seasons |
| Perception of monsoon precipitation           | Whether a respondent correctly perceive a temporal trend in monsoon precipitation                |
| Perception of non-monsoon precipitation       | Whether a respondent correctly perceive a temporal trend in non-monsoon precipitation            |
| Perception of extreme rainy days              | Whether a respondent correctly perceive a temporal trend in precipitation on extreme rainy days  |

<sup>1</sup> An annual calendar in Bangladesh is hypothesized to change from six seasons to four seasons. If a respondent say "yes," this variable is 1, otherwise 0. The definition of this variable is determined on the basis of expert surveys and the inclusion of this variable is important, because this seasonal change is believed to be one reason for frequent flooding.

Table 3: Summary statistics of the variables used in WTP Tobit regressions with 1,011 observations

| Variable                                      | Mean      | Std. dev.  | Min | Max       |
|---|-----------|------------|-----|-----------|
| WTP for 1988 (BDT/year) <sup>0</sup>          | 523.11    | 918.81     | 0   | 5,000     |
| WTP for 1998 (BDT/year)                       | 524.91    | 931.97     | 0   | 5,000     |
| WTP for 2004 (BDT/year)                       | 421.49    | 794.70     | 0   | 5,000     |
| WTP for 2007 (BDT/year)                       | 357.85    | 698.74     | 0   | 5,000     |
| Education <sup>1</sup>                        | 1.10      | 1.19       | 0   | 5         |
| Household income (BDT/year) <sup>2</sup>      | 3.36      | 1.75       | 1   | 8         |
| Household condition <sup>3</sup>              | 2.51      | 0.71       | 0   | 4         |
| Family structure                              | 0.66      | 0.47       | 0   | 1         |
| Residential time <sup>4</sup>                 | 6.1       | 1.3        | 0   | 8         |
| Household members                             | 7.39      | 3.72       | 1   | 27        |
| Household distance from river <sup>5</sup>    | 2.60      | 0.97       | 0   | 6         |
| Loss 1988 (BDT)                               | 77,868.45 | 107,559.60 | 0   | 1,000,000 |
| Loss 1998 (BDT)                               | 56,005.93 | 90,239.90  | 0   | 800,000   |
| Flood preparedness                            | 0.22      | 0.41       | 0   | 1         |
| Knowledge of climate change                   | 0.78      | 0.41       | 0   | 1         |
| Access to flood information                   | 0.53      | 0.50       | 0   | 1         |
| Perception of change from six to four seasons | 0.65      | 0.47       | 0   | 1         |

| Perception of non-monsoon precipitation       | 0.94      | 0.23       | 0   | 1         |
| Perception of extreme rainy days              | 0.84      | 0.36       | 0   | 1         |

<sup>0</sup> BDT represents local currency "Bangladesh taka."

<sup>1</sup> Education is represented by an ordered categorical variable, 0: illiterate, 1: primary, 2: secondary, 3: college, 4: bachelor or university and 5: more than master degree in graduate schools.

<sup>2</sup> Household income is represented by an ordered categorical variable, 0:  $\leq 5,000$ , 1: 5,000-9,999, 2: 10,000-14,999, 3: 15,000-19,999, 4: 20,000-24,999, 5: 25,000-29,999, 6: 30,000-34,999, 7: 35,000-39,999, 8: 40,000 or more.

<sup>3</sup> Household condition represents the degree of strengths in house materials by an ordered categorical variable, 0: slam, 1: bamboo and grass, 2: tin and wood, 3: brick and tin, 4: brick

<sup>4</sup> Residential time represents the years of living in this place by an ordered categorical variable, 0: less than one year, 1: one to three years, 2: three to ten years, 3: ten to twenty years, 4: twenty to thirty years, 5: thirty to forty years, 6: forty to fifty years, 7: fifty to eighty years, 8: more than 80 years.

<sup>5</sup> Household distance from rivers is represented by an ordered categorical variable, 0: less than 100m, 1: 100 to 500m, 2: 500m to 1km, 3: one to two km, 4: two to five km, 5: more than 5km.
